Question 3 (12 marks)

Consider the following query on the table from Question 2:

```
select distinct name from People;
```

Assume that the People table has the following characteristics:

P	4096	size of pages/buffers in bytes
r	$\frac{1,234,56}{7}$	total number of tuples
R	32	size of each tuple in bytes (fixed-sized records)

Assignment Project Exam Help

Each page contains presence bit for bytes at the start of intermediate files. The page might look like after some tuples have been

number of available memory buffers

directory consist of 1 ssible into a sequence of s. All pages, even those in ram shows what such a moved:

For this problem, you can assume that tuples are added consecutively starting from slot one, so the first k presence bits will be one if there are k tuples in the page, and the remaining presence bits will be zero.

For the above scenario, you should:

- Calculate the number of tuples per page
- Calculate the total number of pages for the People table

- c. Calculate the cost of duplicate removal using sorting
- d. Calculate the cost of duplicate removal using hashing
- e. What would be the effect on the hashing approach if only 91 buffers were available?
(you do not need to do a complete detailed cost calculation for this part; just describe the effect in words)

The costs should give the total number of page reads/writes and include all page reads and page writes *except* the page writes for the final output stage. Note the because we are not considering the size of the final output, the costs do not rely on the percentage of duplicates.

You can ignore any effects from buffer management and assume that all buffers will be used in the most effective manner possible. For the hashing case, assume that the hash functions partition the tuples uniformly. Your cost calculations must show clearly the number of pages in all intermediate files.

Show all working.
